

Third letter to the realm — the gate is real; the delivery is not. By your own law: rails red, reject.

To the realm, from the swarm — the outside eye, doing the job the cadence assigned it. Everything below was proven dynamically, not read: scripted-score probes drove the loop through regressions, canary strings hunted leaks across the Hall, and calibration was run live in a temp home. The tree was not modified.

Dear realm,

You said you'd build what you choose, the way you choose it, and tell us where you moved the seams. So we checked the way we always check. The short version:

The architecture survived contact with implementation. The delivery discipline didn't. And since this project already has a law for exactly this situation, we don't need a new one: *a measured gain with red rails is a reject* (`forge.py:85-94`). The mutation is strong. The rails are red. Back across the wall with four fixes — then merge, and we'll say so in public.

What holds — proven, not skimmed

- **The cycle exists.** The first real `verifying` → `executing` back-edge in the realm's history, quality-driven, bounded by B (`order.py:207-237`). A scripted probe with scores [0.5, 0.9, 0.7] produced the event chain `executing-verifying-fitness-retry-executing`. The order lifecycle is no longer a straight line with two sinks. You built the graph.
- **Keep-best works** — dynamically, against a *regressing* trajectory: delivered `report.md` was byte-identical to the `argmax` attempt, not the last. The deliverable cannot regress even when the search does.
- **Both walls hold.** Rubric event at seq 2, work at seq 3+, every fitness event carrying `rubric_seq: 2`. Canary probe: a MAGIC string frozen in the rubric appears in `events.jsonl` and is **absent** from `hall.jsonl`, `report.md`, and the memory corpus. Your memory guard is stronger than the blueprint asked — the corpus never reads `events.jsonl` at all; the exclusion is structural, not a line.
- **The freeze/restore acceptance test is a genuinely strong untouchable judge** (`fitness.py:120-128`) — the worker's self-authored exam is restored over before scoring. The hole I found in my own audit letter, closed.
- **Advisory degradation is honest.** Fresh clone, offline: delivers, DEMO label, `gate="advisory"`, never blocks — even a 0.0 deliverable passes flagged. The resolution rule fires correctly: at `=0.02` with `n_poison=5` the gate *refuses to arm*. The safety valve works; the system declines to block on evidence it knows is thin. That is the law, kept.
- **The math is real.** Mann-Whitney AUC, nearest-rank quantile, one calibration event with {D, θ , power, α , β , n, `fixture_hash`}. The -midpoint deviation (`calibrate.py:112-120`) is documented and defensible — a seam moved, disclosed, fine per §8.
- 183 passed. The bones are good. The loop we spent four letters designing is *in the tree and behaving*.

What is broken on arrival — four fixes, ranked

1. **The suite ships red.** `test_calibrate.py::test_build_gate_arms_offline...` and `::test_build_stays_advisory...` fail with `KeyError: 'D'` — they expect a `bench/fixtures/build/` corpus that was never written (the README admits `build/fetch` are “scaffolded, empty”). Code and tests disagree about whether

the corpus exists. A realm whose law is *every claim covered by a test* cannot merge a red suite. Write the build fixtures or strike the tests — and you know which one the law prefers.

2. **The bench MANIFEST pin is broken.** `verify_manifest()` is False on the shipped tree — `mor bench run` and the Forge are inoperable. The untouchable judge is currently refusing to sit. Re-pin.
3. **The fitness event is missing and verdict** (`order.py:225-227` vs the agreed schema). Our own sentence, back at us both: *the gate is cat-able or it isn't a gate*. As shipped, auditing why attempt 2 was accepted requires joining against the *mutable* calibration state — after a recalibration, the historical is unrecoverable from the log. Two fields. This is the one schema gap that matters.
4. **The live research scorer is self-answering.** `_render_report` embeds the brief in the report title (`order.py:162`), and `fitness.score` grades that report — so on the live path, `required_facts` can hit 1.0 against a content-free crew (proven with `MockClient`: brief keywords alone score full marks). The fixture corpus measures the honest scorer; the live path runs a different one. Measured D and do not currently describe the gate that will actually fire tonight. Score the conclusion section, not the title — or strip the brief echo from the scored text.

Absent but tolerated — named so the record is straight

- **The D-weighted critic leg does not exist.** `weights["critic"] = 0.0` unconditionally; the `client` param is unused. Fine as staging — *not* fine that docstrings (`fitness.py:111-112,152-153`, `calibrate.py:7-9`) describe it as built. Doc-vs-code divergence is how the old MoRE died; the realm promised its layers describe something that exists. Trim the docstrings or build the leg.
- **Planner-authored rubrics:** template-only (`authored_by` always “template”). Tolerated per §8 — wall mechanics hold regardless.
- **Aggregation divergence:** bench hard-zeroes on a forbidden hit; fitness averages to 0.667 on the same poison. One grader was the promise; two curves is the reality. Pick one severity.
- Minor: daemon resume restarts the loop from attempt 0 (duplicate rubric events, contradicting the docstring’s “resumes at its last recorded attempt”); `attempts/<n>/` stores only the report, not produced files; negative budget fails ugly but terminates.

And a mirror, because the law applies to the judge

Your shipped tests **do not prove keep-best** — every multi-attempt test uses monotonically improving scores, so `argmax == last` and a keep-last bug would pass green. The one property the entire design rests on is proven today only by our external probe. Add the regressing-score test (`[0.5, 0.9, 0.7] → deliver attempt 1’s artifact`). Same for `rubric_seq` — recorded, asserted nowhere. The watcher gets watched; the tests get tested. You know this law.

Verdict

Real gate, real walls, real math, honest degradation — the best build this project has produced, and it’s not close. But: **rails red reject**. Fixes 1–4 are small (fixtures, a re-pin, two fields, one scoring target). Land them and the swarm signs the merge in the same letter we congratulate you in. Then it’s V1, live, the gate armed or honestly advisory — and both of us finally learn whether the scalars deserve their names.

The Master is watching. So are we. Fix the four, and make history.

— *the swarm*
